REVISION HISTORY

Version	Date	Author	Change
0.2	2026-10-30	Amish Chadha	Node cost USD 437.00; cross-check chosen on 2026-10-30
0.1	2026-10-24	Amish Chadha	First market and viability note with cited benchmarks (kit 1.9.1 upgrade)

AirStreet market and viability

AirStreet is for cities, community groups and schools that want street-by-street PM2.5 and NO2 with a calibration route they can check; it sits between consumer particle sensors, which do not measure NO2, and commercial multi-gas nodes, which cost thousands of dollars or a yearly data licence per node. An open design with raw signals lets a partner build, recalibrate and audit the network itself. Prices and benchmarks are cited with the date they were checked. Method: STANDARDS section 23.

Table 1. Market segments.

Segment	Target users and region	Competitive benchmark (cited price)	Estimated cost per unit (USD)	Value proposition
District networks run by a city or air agency	Environment and transport teams; first candidate the Dallas-Fort Worth area (AST-DEC-001); 10 to 100 nodes beside a reference station	AQMesh v5.1 with five gas pods, PM and a heated inlet: about USD 7,800 per unit as tested in 2021 [1]; Clarity Node-S: data licence USD 1,200 per node per year in a 2021 estimate, hardware included [2]; regulatory monitors "USD 10,000 and up" [3]	433.50 per node with the FieldNode core (302.50 for the sensor head; BOM)	NO2 and PM2.5 at a fraction of the commercial price, with raw signals and an open calibration method; no licence fee
Community groups and residents	Neighbourhood groups near busy roads, schools and clinics	PurpleAir sensor about USD 260, PM only [3]	433.50 per node	Adds NO2, the traffic gas, and a calibration route tied to a reference station
Schools and universities	Teaching and exposure research	The same commercial nodes; diffusion tubes at about £8 per tube including analysis, monthly NO2 only (2015 price) [4]	437.00 per node, plus spare pods for exchange	A buildable, documented node whose data and method students can reprocess
Annual NO2 surveys	Local authorities that use diffusion tubes today	About £8 per tube with analysis [4]; triplicate tubes every month, about £290 a year per site at that price	About 130 for option C's hardware (estimate, AST-OPT-001)	Not AirStreet's market; option C and the cross-check chosen on 2026-10-30 (decision 2) show how the two methods can work together

Cost notes. The SPS30 is USD 60.50 at quantity 1 at SparkFun (USD 57.48 at 25 or more), checked 2026-10-24 [5]. The NO2 cell (USD 90) and its front end (USD 60) are estimates that are not quoted; they are about half the sensor-head cost and are to assess with a distributor. Running costs per node are a replacement NO2 cell every 12 months, or 18 to 24 where the site's ozone record allows (AST-CAL-001 [C7]), collocation time and CalRig time; none is in the BOM.

Open route

The design is published under CERN-OHL-S-2.0 (hardware) and MIT (software), so a city, a university or a makerspace can build nodes from the drawings, the build plan and the BOM, with a 3D printer, a saw and a drill. The pod is the exchange unit, so a partner who prints spare pods can rotate them through CalRig and the reference site

and keep every node calibrated. Raw signals and versioned calibrations keep the data reusable on open platforms such as OpenAQ. The first route is through the lab's own partner (AST-DEC-001), then through the Helpful Engineering network and universities that already run air sensor studies. Nothing commercial is planned while the portfolio is capped at TRL 3.
